

Lists: implementation/implications

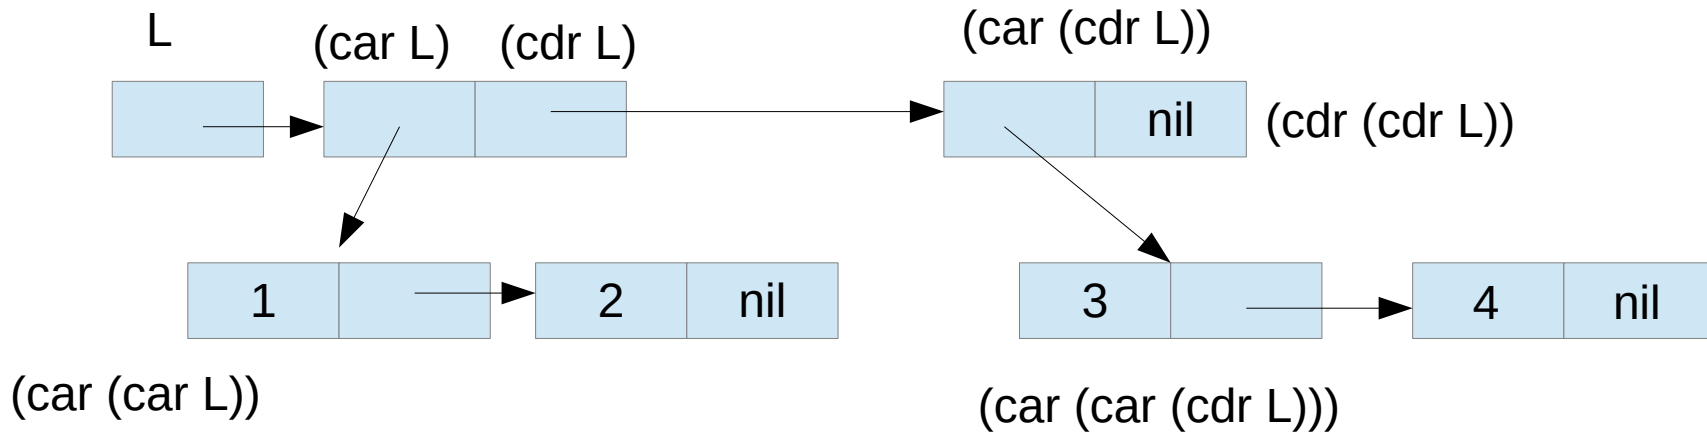

- For primitive data types (e.g. characters, integers, reals, booleans), items can be held in a simple 32- or 64-bit cell
- For lists, however, lisp adopts a linked-list approach, where it stores a pointer to the front of the list (nil if the list is empty)
- Each list element is represented as two parts: the value of that element (accessible through car) and a pointer to the next element (accessible through cdr)
- If a list element is itself a list, then the “value of the element” would be a pointer to the front element of that list

Pointer-based representation

- Consider (defvar L '(1 2 3 4))

Nested lists

- `(defvar L '((1 2) (3 4)))`

setf on car, cdr

- (car X) and (cdr X) can be altered with setf

```
(defvar L '(1 2 3))
```

```
(setf (car L) 5)
```

```
(setf (cdr (cdr L)) nil)
```

Shallow copy of a list

- `(defvar L '(1 2)) (defvar X L)`

- `(setf (car X) 10)` changes front element to 10 for L as well, since L and X really refer to the same internal list
- `(setf X 10)` changes X to 10, has no effect on list L refers to

Passing a list to a function

```
(defvar L '(1 2 3))  
(defun f ( x ) (setf x 10))  
(defun g ( x ) (setf (car x) 10))  
(f L) ; no effect  
(g L) ; changes first element to 10
```

(cons e L)

```
(defvar L '(1 2 3))
```

```
(defun X (cons 4 L))
```

Circular lists

- we can create circular lists

```
(defvar L '(10 20 30))
```

```
(setf (cddddr L) L) ; make end of L point to front of L
```

```
(nth 3 L) ; returns 10
```

```
(nth 4 L) ; returns 20, etc
```

```
(format "~A~%" L) ; goes into infinite loop
```

- Can turn on cycle-detection so it doesn't infinite loop

```
(let ((*print-circle* t)) (format t "~A~%" L))
```

```
; actually prints "#0=(10 20 30 . #0#)
```
